Review

MLE vs MAP

Maximum Likelihood Estimation

$$\begin{aligned}\theta_{\text{MLE}} &= \operatorname{argmax}_{\theta} f(X_1, X_2, \dots, X_n | \theta) \\ &= \operatorname{argmax}_{\theta} \sum_i \log f(X_i | \theta)\end{aligned}$$

Maximum A Posteriori

$$\begin{aligned}\theta_{\text{MAP}} &= \operatorname{argmax}_{\theta} f(\theta | X_1, X_2, \dots, X_n) \\ &= \operatorname{argmax}_{\theta} \left(\log g(\theta) + \sum_i \log f(X_i | \theta) \right)\end{aligned}$$

Multinomial with Laplace Smoothing

$$\begin{aligned}\theta_{\text{MAP}} &= \underset{\theta}{\operatorname{argmax}} f(\theta | X_1, X_2, \dots, X_n) \\ &= \underset{\theta}{\operatorname{argmax}} \left(\log g(\theta) + \sum_i \log f(X_i | \theta) \right)\end{aligned}$$

MAP estimate of
the probability of
outcome i

number of
observed outcomes
of type i

$$p_i = \frac{x_i + 1}{n + m}$$

number of observations

number of outcome types

The last estimator has risen...

Machine Learning

Machine Learning: Formally

- Many different forms of “Machine Learning”
 - We focus on the problem of *prediction*
- Want to make a prediction based on observations
 - Vector \mathbf{X} of m observed variables: $\mathbf{X} = [X_1 \dots X_m]$
 - Based on observed \mathbf{X} , want to predict unseen variable \mathbf{Y}
 - \mathbf{Y} called “output feature/variable” (or the “dependent variable”)
 - Seek to “learn” a function $g(\mathbf{X})$ to predict \mathbf{Y} :
 - $\hat{\mathbf{Y}} = g(\mathbf{X})$
 - When \mathbf{Y} is discrete, prediction of \mathbf{Y} is called “classification”
 - When \mathbf{Y} is continuous, prediction of \mathbf{Y} is called “regression”

Training Data

Assume IID data:

N training datapoints

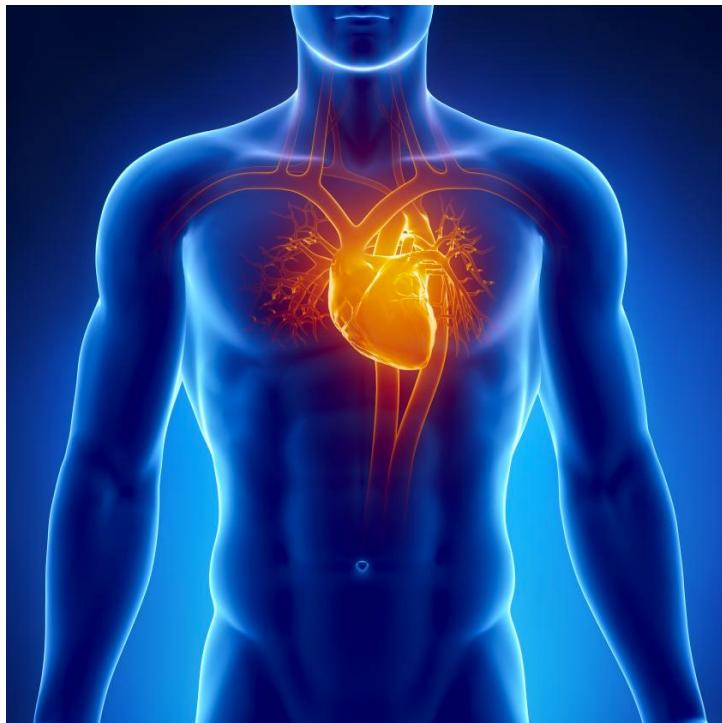

$$(\mathbf{x}^{(1)}, y^{(1)}), (\mathbf{x}^{(2)}, y^{(2)}), \dots (\mathbf{x}^{(n)}, y^{(n)})$$

$$m = |\mathbf{x}^{(i)}|$$

Each datapoint has m features and a single output

Training Data

Assume IID data:

N training datapoints

$$(\mathbf{x}^{(1)}, y^{(1)}), (\mathbf{x}^{(2)}, y^{(2)}), \dots (\mathbf{x}^{(n)}, y^{(n)})$$

$$m = |\mathbf{x}^{(i)}|$$

Each datapoint has m features and a single output

ML is ubiquitous

Linear Regression

A Grounding Example: Linear Regression

Problem: Predict real value Y based on observing variable X

N training pairs: $(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \dots, (x^{(n)}, y^{(n)})$

Model: Linear weight for every feature

$$\begin{aligned}\hat{Y} &= \theta_1 X_1 + \theta_2 X_2 + \dots \theta_{n-1} X_{n-1} + \theta_n 1 \\ &= \boldsymbol{\theta}^T \mathbf{X}\end{aligned}$$

Training: Chose the best thetas to describe your data

$$\hat{\theta}_{MLE} = \underset{\boldsymbol{\theta}}{\operatorname{argmax}} - \sum_{i=1}^n (y^{(i)} - \boldsymbol{\theta}^T \mathbf{x}^{(i)})^2$$

Use Gradient Ascent to optimize

MLE based on
assumption

$$\begin{aligned}Y &= \hat{Y} + Z \\ Z &\sim N(0, \sigma^2)\end{aligned}$$

Predicting Warriors

X_1 = Opposing team ELO

X_2 = Points in last game

X_3 = Curry playing?

X_4 = Playing at home?

Y = Warriors points

Predicting CO₂

X₁ = Temperature

X₂ = Elevation

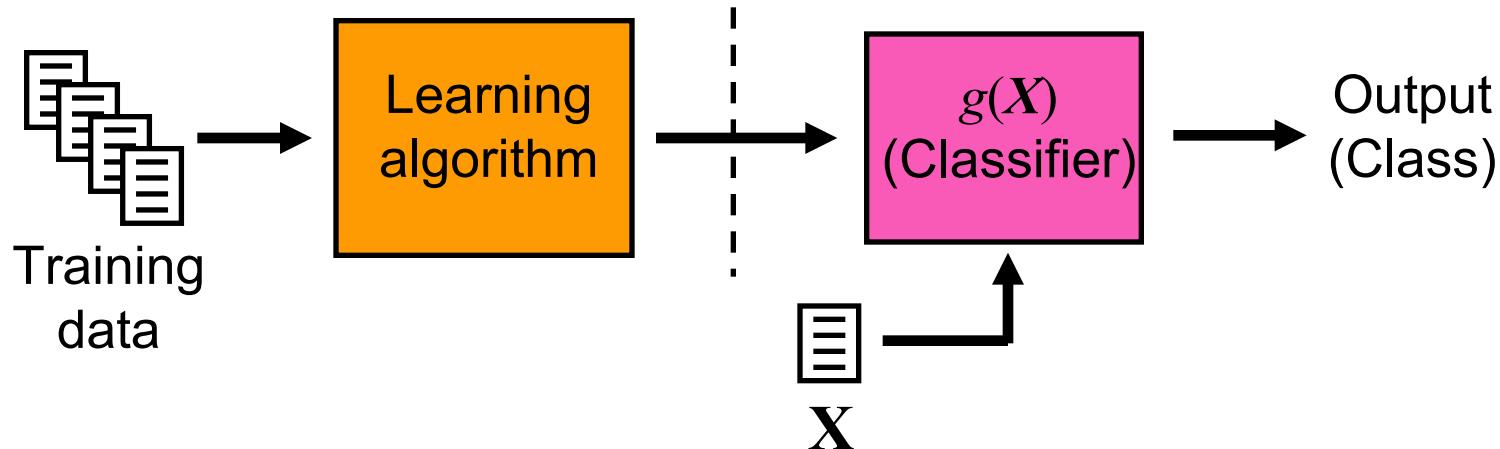

X₃ = CO₂ level yesterday

X₄ = GDP of region

X₅ = Acres of forest growth

Y = CO₂ levels

The Machine Learning Process

- Training data: set of n pre-classified data instances
 - n training pairs: $(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), \dots, (x^{(n)}, y^{(n)})$
 - Use superscripts to denote i -th training instance
- Learning algorithm: method for determining $g(X)$
 - Given a new input observation of $x = x_1, x_2, \dots, x_m$
 - Use $g(x)$ to compute a corresponding output (prediction)

Predicting Warriors

$Y = \text{Warriors points}$

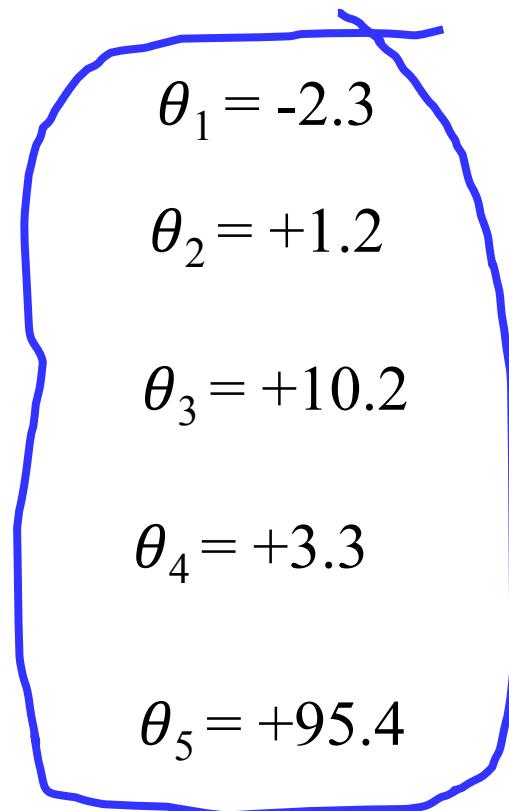

$$\begin{aligned}\hat{Y} &= \theta_1 X_1 + \theta_2 X_2 + \dots \theta_{n-1} X_{n-1} + \theta_n 1 \\ &= \boldsymbol{\theta}^T \mathbf{X}\end{aligned}$$

$X_1 = \text{Opposing team ELO}$

$X_2 = \text{Points in last game}$

$X_3 = \text{Curry playing?}$

$X_4 = \text{Playing at home?}$

Classification

Assuming each feature
is binary...

Not going to cut it!

What is the problem here?

$$\begin{aligned}\hat{y} &= \operatorname{argmax}_{y=\{0,1\}} P(y|\mathbf{x}) \\ &= \operatorname{argmax}_{y=\{0,1\}} \frac{P(\mathbf{x}|y)P(y)}{P(\mathbf{x})} \\ &= \operatorname{argmax}_{y=\{0,1\}} P(\mathbf{x}|y)P(y)\end{aligned}$$

$$P(\mathbf{x}|y) = P(x_1, x_2, \dots, x_m | y)$$

Naïve Bayes Assumption

$$\begin{aligned}\hat{y} &= \operatorname{argmax}_{y=\{0,1\}} P(y|\mathbf{x}) \\&= \operatorname{argmax}_{y=\{0,1\}} \frac{P(\mathbf{x}|y)P(y)}{P(\mathbf{x})} \\&= \operatorname{argmax}_{y=\{0,1\}} P(\mathbf{x}|y)P(y)\end{aligned}$$

$$P(\mathbf{x}|y) = P(x_1, x_2, \dots, x_m|y)$$

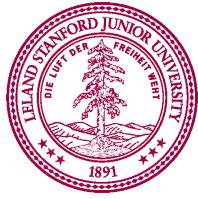

$$= \prod_i P(x_i|y)$$

The Naïve Bayes
assumption

Naïve Bayes Assumption:

$$P(\mathbf{x}|y) = \prod_i P(x_i|y)$$

Naïve Bayes Classifier

Naïve Bayes Classifier

- Say, we have m input values $\mathbf{X} = \langle X_1, X_2, \dots, X_m \rangle$
 - Assume variables X_1, X_2, \dots, X_m are conditionally independent given Y
 - Really don't believe X_1, X_2, \dots, X_m are conditionally independent
 - Just an approximation we make to be able to make predictions
 - This is called the “Naive Bayes” assumption, hence the name
 - Predict Y using $\hat{Y} = \arg \max_y P(\mathbf{X}, Y) = \arg \max_y P(\mathbf{X} | Y)P(Y)$
 - But, we now have:
$$P(\mathbf{X} | Y) = P(X_1, X_2, \dots, X_m | Y) = \prod_{i=1}^m P(X_i | Y) \text{ by conditional independence}$$
 - Note: computation of PMF table is linear in $m : O(m)$
 - Don't need much data to get good probability estimates

Naïve Bayes Example

- Predict Y based on observing variables X_1 and X_2
 - X_1 and X_2 are both indicator variables
 - X_1 denotes “likes Star Wars”, X_2 denotes “likes Harry Potter”
 - Y is indicator variable: “likes Lord of the Rings”
 - Use training data to estimate PMFs: $\hat{P}_{X_i,Y}(x_i, y)$, $\hat{P}_Y(y)$

		X_1		MLE estimates		X_2		MLE estimates		Y	#	MLE est.	
		0	1	0	1	0	1	0	1	0	13	0.43	
Y	0	3	10	0.10	0.33	0	5	8	0.17	0.27	0	13	0.43
	1	4	13	0.13	0.43	1	7	10	0.23	0.33	1	17	0.57

- Say someone likes Star Wars ($X_1 = 1$), but not Harry Potter ($X_2 = 0$)
- Will they like “Lord of the Rings”? Need to predict Y :

$$\hat{Y} = \arg \max_y \hat{P}(\mathbf{X} | Y) \hat{P}(Y) = \arg \max_y \hat{P}(X_1 | Y) \hat{P}(X_2 | Y) \hat{P}(Y)$$

One SciFi/Fantasy to Rule them All

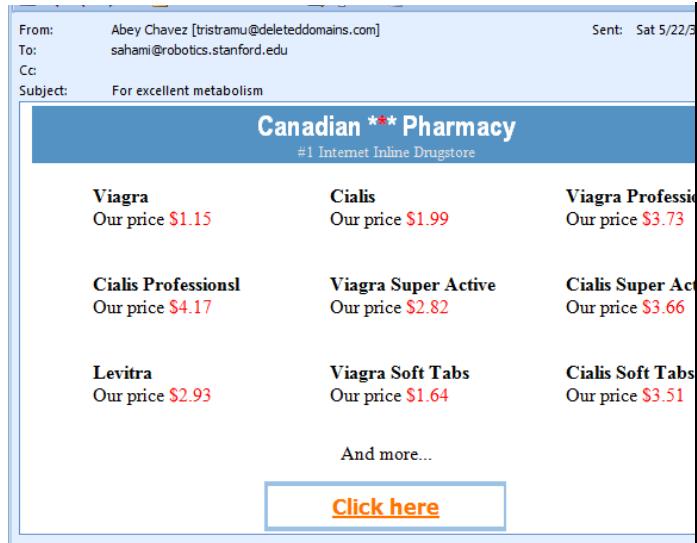

X_1	0	1	MLE estimates		X_2	0	1	MLE estimates		Y	#	MLE est.
Y			0.10	0.33	Y			0.17	0.27	0	13	0.43
0	3	10	0.10	0.33	0	5	8	0.17	0.27	0	13	0.43
1	4	13	0.13	0.43	1	7	10	0.23	0.33	1	17	0.57

- Prediction for Y is value of Y maximizing $P(\mathbf{X}, Y)$:

$$\hat{Y} = \arg \max_y \hat{P}(\mathbf{X} | Y) \hat{P}(Y) = \arg \max_y \hat{P}(X_1 | Y) \hat{P}(X_2 | Y) \hat{P}(Y)$$
 - Compute $P(\mathbf{X}, Y=0)$: $\hat{P}(X_1 = 1 | Y = 0) \hat{P}(X_2 = 0 | Y = 0) \hat{P}(Y = 0)$
 $= \frac{\hat{P}(X_1 = 1, Y = 0)}{\hat{P}(Y = 0)} \frac{\hat{P}(X_2 = 0, Y = 0)}{\hat{P}(Y = 0)} \hat{P}(Y = 0) \approx \frac{0.33}{0.43} \frac{0.17}{0.43} 0.43 \approx 0.13$
 - Compute $P(\mathbf{X}, Y=1)$: $\hat{P}(X_1 = 1 | Y = 1) \hat{P}(X_2 = 0 | Y = 1) \hat{P}(Y = 1)$
 $= \frac{\hat{P}(X_1 = 1, Y = 1)}{\hat{P}(Y = 1)} \frac{\hat{P}(X_2 = 0, Y = 1)}{\hat{P}(Y = 1)} \hat{P}(Y = 1) \approx \frac{0.43}{0.57} \frac{0.23}{0.57} 0.57 \approx 0.17$
 - Since $P(\mathbf{X}, Y=1) > P(\mathbf{X}, Y=0)$, we predict $\hat{Y} = 1$

Abstract

In addressing the growing problem of junk E-mail on the Internet, we examine methods for the automated

contain offensive material (such as graphic pornography), there is often a higher cost to users of actually viewing this mail than simply the time to sort out the junk. Lastly, junk mail not only wastes user time, but

Spam, Spam... Go Away!

- The constant battle with spam

- Spam prevalence: % of all incoming Gmail traffic (before filtering) that is spam
- Missed spam: % of total spam reported by Gmail users

As the amount of spam has increased, Gmail users have received less of it in their inboxes, reporting a rate less than 1%.

“And machine-learning algorithms developed to merge and rank large sets of Google search results allow us to combine hundreds of factors to classify spam.”

Email Classification

- Want to predict if an email is spam or not
 - Start with the input data
 - Consider a lexicon of m words (Note: in English $m \approx 100,000$)
 - Define m indicator variables $\mathbf{X} = \langle X_1, X_2, \dots, X_m \rangle$
 - Each variable X_i denotes if word i appeared in a document or not
 - Note: m is huge, so make “Naive Bayes” assumption
 - Define output classes Y to be: {spam, non-spam}
 - Given training set of N previous emails
 - For each email message, we have a training instance: $\mathbf{X} = \langle X_1, X_2, \dots, X_m \rangle$ noting for each word, if it appeared in email
 - Each email message is also marked as spam or not (value of Y)

Training the Classifier

- Given N training pairs:

$$(\mathbf{x}^{(1)}, y^{(1)}), (\mathbf{x}^{(2)}, y^{(2)}), \dots, (\mathbf{x}^{(n)}, y^{(n)})$$

- Learning
 - Estimate probabilities $P(Y)$ and each $P(X_i | Y)$ for all i
 - Many words are likely to not appear at all in given set of email
 - Laplace estimate: $\hat{p}(X_i = 1 | Y = \text{spam})_{\text{Laplace}} = \frac{(\# \text{spam emails with word } i) + 1}{\text{total # spam emails} + 2}$
- Classification
 - For a new email, generate $\mathbf{X} = \langle X_1, X_2, \dots, X_m \rangle$
 - Classify as spam or not using: $\hat{Y} = \arg \max_y \hat{P}(\mathbf{X} | Y) \hat{P}(Y)$
 - Employ Naive Bayes assumption: $\hat{P}(\mathbf{X} | Y) = \prod_{i=1}^m \hat{P}(X_i | Y)$

Training Naïve Bayes, is estimating parameters for a multinomial.

Thus it is just counting.

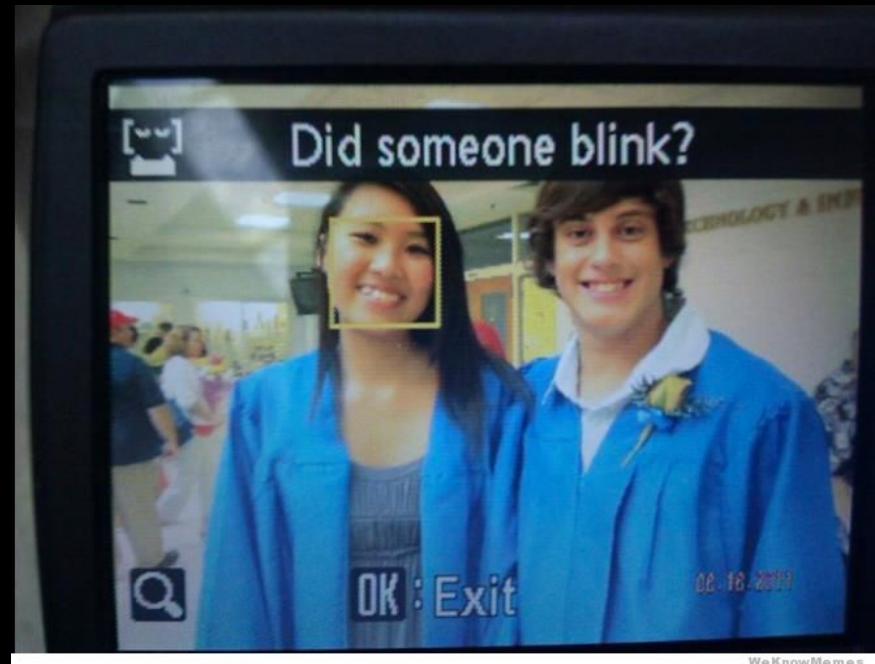

How Does This Do?

- After training, can test with another set of data
 - “Testing” set also has known values for Y, so we can see how often we were right/wrong in predictions for Y
 - Spam data
 - Email data set: 1789 emails (1578 spam, 211 non-spam)
 - First, 1538 email messages (by time) used for training
 - Next 251 messages used to test learned classifier
 - Criteria:
 - Precision = # *correctly* predicted class Y / # predicted class Y
 - Recall = # *correctly* predicted class Y / # real class Y messages

	Spam		Non-spam	
	Precision	Recall	Precision	Recall
Words only	97.1%	94.3%	87.7%	93.4%
Words + add'l features	100%	98.3%	96.2%	100%

On biased datasets

Ethics and Datasets?

Sometimes machine learning feels universally unbiased.

We can even prove our estimators are “unbiased” 😊

Google/Nikon/HP had biased datasets

Ancestry dataset prediction

East Asian

or

Ad Mixed American (Native, European and
African Americans)

It is much easier
to write a binary classifier
when learning ML
for the first time

Learn Three Things From This

1. What classification with DNA Single Nucleotide Polymorphisms looks like.
2. That genetic ancestry paints a more realistic picture of how we are mixed in many nuanced ways.
3. The importance of choosing the right data to learn from. Your results will be as biased as your dataset.

Know it so you can beat it!

Ethics in Machine Learning
is a whole new field
